Table 1: The Statistics of datasets.

2 Metrics

For a principled evaluation, we consider two metrics, \textit{average accuracy} (↑) and \textit{forgetting measure} (↓) \cite{1}, to evaluate the performance of models on test data of all tasks. The average accuracy evaluates the overall performance for all seen tasks, while the forgetting measure reflects the accuracy drops on previous tasks after the model is trained on new tasks. The large forgetting values signify the model has less stability when encountering new tasks.

Suppose we have a sequence of tasks with identifier $t \in \{1, \cdots, T\}$ and denote $R_{t,j}$ the classification accuracy of the model on test data of task $j$ after learning the training data up till task $i$. The two metrics are defined as follows.

2.1 Average Accuracy (↑)

\[
ACC_t = \frac{1}{t} \sum_{k=1}^{t} R_{t,k}
\]  

The above definition indicates the average accuracy on test data of task 1 to $t$ after the model has learned continually up till task $t$, the values of which are used to draw the accuracy

2.2 Forgetting Measure ($\downarrow$)

$$FGT_t = \frac{1}{t-1} \sum_{k=1}^{t-1} r_{t,k}$$ (2)

where $r_{t,k}$ is the forgetting on task $k$ after the model has been trained continually up till task $t$, which is calculated as follows,

$$r_{t,k} = \max_{i \in \{1, \ldots, t-1\}} R_{i,k} - R_{t,k}$$ (3)

The forgetting measures the accuracy drops on previous tasks after the model is trained on new tasks. The large forgetting values signify the model has less stability when encountering new tasks. The results for the forgetting measure are reported in Table 2. CCL-FP+ produces the best performance on a majority of cases compared to other CL competitors, demonstrating the overall outstanding ability of our model to overcome catastrophic forgetting even with a very small buffer.

3 Upper Bound

Single epoch training is a very compelling and ideal setup for continual learning and somewhat close to the spirit why we focus on general continual learning [6]. However, Joint, as an upper bound for continual learning, suffers underfitting to some extent in this setting. In Table 3, we compare the results of joint training in the online (single-epoch) and offline (multi-epoch) setups.
Table 4: The average accuracy (%) for our model CCL-FP+ and SCR across 5 runs with different random seeds. Part of numbers in this table are used to generate Figure 4 (paper) and Table 4 (paper).

| $|B_M|$ | M=0.2k SCR Ours | M=0.5k SCR Ours | M=1k SCR Ours | M=5k SCR Ours |
|-------|------------------|------------------|----------------|----------------|
| 10    | 40.91 50.11      | 45.19 57.03      | 46.05 60.29    | 46.12 63.84    |
| 20    | 38.85 48.24      | 48.83 56.89      | 49.24 63.63    | 52.67 67.17    |
| 50    | 31.26 43.77      | 45.66 54.43      | 57.27 65.77    | 64.72 72.33    |
| 100   | 30.31 44.08      | 45.29 53.18      | 55.78 62.37    | 68.67 75.86    |
| 200   | 31.28 37.57      | 43.68 49.25      | 55.43 58.47    | 72.91 75.17    |

Figure 1: Impact of the memory batch size on the Split CIFAR-10 dataset in the class incremental setting. M is the memory buffer size.

4 Comparison with SCR

We further study the impact of different memory batch size in cases of different buffer size for our model CCL-FP+ and SCR on the Split CIFAR-10 dataset in the class incremental setting. As we can see in Table 4, the small memory batch size is preferable when the buffer size is small, e.g. the performance achieves the best when $|B_M|=10$ for M=0.2k and starts to drop when $|B_M|≥20$. For M=1k, $|B_M|=50$ is preferable and for M=5k, $|B_M|=100$ is desirable.

Generally speaking, contrastive representation learning benefits from larger memory batch size since it means more negative samples [3, 4, 5]. As we can see in Figure 1, when the buffer size is large, e.g. M=5k, the performance significantly improves with the increase of memory batch size and achieves the best when $B_M=100$. However, in the case of small buffer size, e.g. M=0.2k, large memory batch size can observably degrade the performance because the model may easily overfit the memory data. Furthermore, we compare our model CCL-FP+ with SCR [5] on S-CIFAR-10 and S-CIFAR-100 datasets in the class incremental setting with memory batch size of 10 and 100. As shown in Table 5, our model CCL-FP+ consistently outperforms SCR in all cases.

5 Hyperparameter Sensitivity

We report the sensitivity of CCL-FP+ to hyperparameters $w$, $\alpha$, $\beta$ in terms of average accuracy on the Split CIFAR-10 dataset in the class incremental setting in Table 6. As shown, a larger value of $w$ contributes to better performance demonstrating the appreciable impact of feature propagation. The model is not overly sensitive to $\alpha$ and $\beta$. Generally, $\alpha ≤ 0.5$ yields decent performance. The large value of $\alpha$ may degrade the performance as a result of overly protecting the representation space for past tasks and impairing the strength to adapt to new
Table 5: The comparison of average accuracy of SCR and CCL-FP+ with different memory batch size (10 vs. 100) on Split CIFAR-10 (up) and Split CIFAR-100 (down) datasets in the class incremental setting. M is the memory buffer size.

6 2D t-SNE Visualization

Figure 2 presents the visualization results of CCL-FP+ and ER on P-MNIST. Each class/color is consist of images from 20 tasks. The representations learned by CCL-FP+ are better separable compared with ER.

7 Algorithm

Algorithm 1 provides a pseudocode for CCL-FP+. CCL-FP is easily achieved by removing the step of supervised contrastive loss. Algorithm 2 describes the procedure of reservoir sampling [1, 2].
Algorithm 1 Training of CCL-FP+

Input: Sequential dataset $D = \{D_1, \cdots, D_T\}$, batch size $b$, learning rate $\lambda$, scalars $w, \alpha, \beta$

1: $\mathcal{M} \leftarrow \{\}$ 
2: $\theta_o \leftarrow$ None, $\theta \leftarrow$ Rand. Init.
3: $\theta$: parameters of $f$ and $\psi$ // classifier $f$ and feature extractor $\psi$
4: for $t \in \{1, \cdots, T\}$ do
5:   for $B \sim D_t$ do // sample a minibatch of size $b$ from current dataset
6:     $B_M \sim \mathcal{M}$ // sample a minibatch of size $b$ from memory set
7:     if $\theta_o$ is None then
8:       $L_{ce} \leftarrow l_{ce}(f(\psi(B \cup B_M)))$ // standard cross-entropy loss
9:       $L_{scl} \leftarrow l_{scl}(\psi(B \cup B_M))$ // supervised contrastive loss
10:      $L \leftarrow L_{ce} + \beta \cdot L_{scl}$
11:    else
12:       $\tilde{\psi}(B \cup B_M) \leftarrow w \cdot \psi(B \cup B_M) + (1 - w) \cdot \psi_o(B \cup B_M)$ // modify representation using feature propagation
13:       $L_{ce} \leftarrow l_{ce}(f(\tilde{\psi}(B \cup B_M)))$ // the cross-entropy loss on modified representation
14:       $L_{cl} \leftarrow l_{cl}(\psi(B \cup B_M), \psi_o(B \cup B_M))$ // contrastive loss on current and previous representation
15:       $L_{scl} \leftarrow l_{scl}(\psi(B \cup B_M))$ // supervised contrastive loss
16:       $L \leftarrow L_{ce} + \alpha \cdot L_{cl} + \beta \cdot L_{scl}$
17:    end if
18:     $\theta \leftarrow \theta - \lambda \cdot \nabla \theta L$ // single SGD step to update parameters
19:   end for
20:   $\mathcal{M} \leftarrow$ reservoir($\mathcal{M}, B$) // update memory set using reservoir sampling
21: end for
22: return $\theta$

Algorithm 2 Reservoir Sampling

Input: The memory set $\mathcal{M}$, number of seen examples $N$, example $(x, y, t)$

1: if $|\mathcal{M}| > N$ then
2:   $\mathcal{M}[N] \leftarrow (x, y, t)$
3: else
4:   $i = \text{randint}(0, N)$
5:   if $i < |\mathcal{M}|$ then
6:     $\mathcal{M}[i] \leftarrow (x, y, t)$ // overwrite memory slot
7:   end if
8: end if
